Carbon Footprint

Carbon Footprint

Calculation of Carbon Footprint for Travel

Problem Statement:

Pollution is one of the problems that currently concerns scientists the most.

One of the ways we can reduce the footprint of pollutants is by studying their impact. Carbon dioxide (CO₂) is one of these pollutants. In this exercise, the creation of a program is proposed that calculates the CO₂ generated by different means of transport during a trip. The program should ask the user to enter the type of transportation (car, train, plane, ship), the distance of the trip, and the

number of passengers, and calculate, according to the attached table (see Table 1) and display the amount of CO₂ emissions associated with that trip.

Contest – January 26th 2024

Carbon Footprint

CO2 Emission Table According to Each Transport for Each Kilometer and Person Transported:

Transport	Emission of Kg of CO2 per km and per passenger transported
coche	0.12
tren	0.05
avion	0.25
barco	0.20

Table 1. CO2 Emission Data

Input and Output

Input Format:

The input will consist of a single line with the name of the transport, a space, the number of kilometers traveled, a space, and finally the number of people transported.

The data entered will always follow this format and the indicated transport must always be one of those found in the table.

Output Format:

The program will display the CO2 emission produced according to the data in the table, the number of kilometers traveled, and people transported.

Carbon Footprint

Examples of Input and Output

Example 1

Input

coche 100 2

Output:

24

Example 2

Input:

tren 200 100

Output:

1000

Example 3

Input:

barco 67.5 233

Output:

3145.5
